Appendix B	SQL Validation Snapshot

1. Executive Summary

This project analyzes 166 recorded customer leads captured by Deblocar between June and September 2026. The analysis follows an end-to-end business analytics workflow: source Excel data were consolidated and cleaned with Python, validated and queried in MySQL, and translated into a two-page Power BI dashboard focused on acquisition, service demand and lead management.

166	23	54	62	13.86%
RECORDED LEADS	RECORDED COMPLETIONS	APPOINTMENTS CONFIRMED	LEADS IN PROGRESS	RECORDED COMPLETION RATE

The acquisition picture is concentrated: Messenger generated 63 leads and WhatsApp 53, together representing 116 leads (69.9%). WhatsApp is also associated with 19 of the 23 recorded completions (82.6%). Within WhatsApp-recorded leads, 19 of 53 were marked completed (35.8%), while Messenger recorded 1 completion among 63 leads (1.6%). These figures are descriptive associations, not evidence that the channel itself caused the different outcomes.

Demand is similarly concentrated. The three largest standardized service categories—Fonctions cachées (42), Navigation GPS (23), and Apple CarPlay (21)—account for 86 of 166 leads (51.8%). This concentration can inform service preparation, content planning and follow-up prioritization.

The current lead-management snapshot shows 62 leads in progress and 54 appointments confirmed. Together, these two groups account for 116 leads (69.9%) and represent the largest operational pool for follow-up. Because the dataset records the latest known status rather than every historical stage transition, the 13.86% figure must be treated as a recorded completion rate—not as a conventional conversion rate.

EXECUTIVE IMPLICATION

The most immediate opportunity is not simply to generate more leads; it is to improve the consistency and visibility of follow-up on the existing pipeline, while investigating why WhatsApp-recorded leads show substantially more recorded completions than other sources.

2. Business Context

Deblocar operates in a service environment where customer requests are captured through multiple communication channels and translated into vehicle-related services such as hidden-function activation, navigation, Apple CarPlay and other configuration or diagnostic services. The operational dataset used for this project is a lead-tracking workbook containing monthly sheets and customer-request fields.

From a community-management and customer-growth perspective, the business needs visibility into three connected questions: where demand comes from, what customers are asking for, and what happens to those leads after they enter the pipeline. The purpose of this analysis is therefore to convert operational lead records into a management view that can support channel follow-up, service prioritization, data-quality improvements and workload planning.

Business questions

- Which acquisition sources generate the largest volume of recorded leads?
- Which acquisition sources are associated with recorded service completions?
- Which services generate the strongest customer demand?
- Where is the current lead pipeline concentrated by status?
- Which operational bottlenecks or data-quality gaps reduce visibility?
- What practical actions can improve follow-up, service preparation and future measurement?

3. Objectives

The project objectives were defined to connect the analysis directly to operational decision-making.

- Measure lead volume and acquisition-source distribution across the available period.
- Identify the services most frequently requested by customers.
- Describe the current status of the lead pipeline and quantify recorded completions.
- Compare recorded completions across acquisition sources and service categories.
- Identify data-quality issues that limit reliable customer-growth measurement.
- Translate the findings into practical recommendations for community management, customer follow-up and management reporting.
- Build a reusable analytical workflow combining Python, SQL and Power BI rather than relying on a one-off spreadsheet review.

ANALYTICAL PRINCIPLE

The report distinguishes observed facts from interpretation. In particular, source-to-completion differences are treated as associations; the data do not establish causal effects of acquisition channels.

4. Data & Methodology

4.1 Dataset scope

Item	Value
Source workbook	Deblocar lead-tracking Excel workbook
Analysis period	June–September 2026
Recorded leads	166
Meaningful monthly tabs	June, July, August, September
Excluded from analysis	Blank/template monthly tabs
Public-analysis dataset	Anonymized lead-level data

4.2 End-to-end workflow

Stage	Tool	Purpose
1. Data consolidation	Python / pandas	Combine monthly sheets into one analysis table.
2. Data inspection	Python	Inspect fields, missingness, inconsistent labels and duplicates.
3. Cleaning & standardization	Python	Standardize sources, statuses and clearly equivalent service labels.
4. Anonymization	Python	Remove names, phone numbers, VINs, activation codes and notes from the analysis-ready public dataset.
5. SQL validation	MySQL	Load 166 records and validate core business metrics with reproducible queries.
6. Dashboarding	Power BI	Present acquisition, service demand and lead-management KPIs.
7. Recommendations	Business analysis	Translate descriptive findings into operational actions.

4.3 Cleaning decisions

Missing values were retained rather than deleting leads.

Lead-source labels were standardized to Messenger, WhatsApp, Instagram and Appel direct; missing sources were retained as Missing in reporting.

Status values were grouped into operational categories while preserving the distinction between completed, in-progress, confirmed appointments, cancelled and not-feasible leads.

Only clear service-label variations were standardized; semantically different combinations were not aggressively merged.

Repeated phone numbers and VINs were flagged for review rather than automatically treated as duplicate customers.

Direct identifiers and free-text notes were removed from the anonymized analysis dataset.

4.4 Status interpretation

Done = service completed.

Cancelled = customer cancelled.

Non faisable = lead became infeasible after vehicle/service verification.

RDV honoré = appointment attended; completion was not verified in the dataset.

Statuses represent a current snapshot, not a complete historical conversion funnel.

5. Lead Acquisition Analysis

5.1 Lead volume over time

Month	Recorded leads	Share of total
June	54	32.5%
July	76	45.8%
August	29	17.5%
September	7	4.2%
Total	166	100.0%

July is the highest-volume month with 76 recorded leads, representing 45.8% of the available dataset. Volume then falls to 29 in August and 7 in September. September should not be interpreted as a full-month performance benchmark because the source workbook contains only seven recorded leads for that month.

5.2 Acquisition-source distribution

Source	Leads	Share
Messenger	63	38.0%
WhatsApp	53	31.9%
Instagram	26	15.7%
Missing	17	10.2%
Appel direct	7	4.2%
Total	166	100.0%

Messenger and WhatsApp together account for 116 leads, or 69.9% of all recorded leads. This means community-management effort and response processes on these two channels cover the majority of observed acquisition volume.

5.3 Recorded completions by source

Source	Recorded leads	Completed	Completion within source
WhatsApp	53	19	35.8%

Instagram	26	2	7.7%
Missing	17	1	5.9%
Messenger	63	1	1.6%
Appel direct	7	0	0.0%

WhatsApp accounts for 19 of the 23 recorded completions (82.6%). Messenger has the largest lead volume but only one recorded completion. This contrast is strategically important, but it should trigger investigation rather than an automatic channel reallocation: channel mix, customer intent, response time, qualification quality, staff handling and status-recording practices could all contribute.

ACQUISITION ACTION

Use WhatsApp as a benchmark for investigating what effective handling looks like—response speed, qualification questions, follow-up cadence and customer intent—then test whether the same operating practices improve outcomes on other channels.

6. Service Demand Analysis

6.1 Most requested services

Service category	Requests	Share of all leads
Fonctions cachées	42	25.3%
Navigation GPS	23	13.9%
Apple CarPlay	21	12.7%
Missing	20	12.0%
Navigation + Apple CarPlay	6	3.6%
Navigation	6	3.6%
Navigation + Android Auto	5	3.0%
Activation alarme	4	2.4%
Autre	4	2.4%
Diagnostique	4	2.4%

The three largest standardized service categories—Fonctions cachées, Navigation GPS and Apple CarPlay—represent 86 of the 166 leads (51.8%). This concentration gives Deblocar a clear basis for prioritizing content, FAQs, service preparation and response scripts.

6.2 Recorded completions by service

Service category	Recorded completions
Fonctions cachées	6
Navigation GPS	3
Diagnostique	2
Activation alarme	2
Navigation	1
Apple CarPlay	1
Other individual service categories	8
Total	23

Fonctions cachées and Navigation GPS together account for 9 of the 23 recorded completions (39.1%). Some small service categories show high apparent completion proportions because they contain only a few observations; these small-n percentages should not be used as standalone performance benchmarks.

6.3 Service-demand implication

Prepare reusable customer-facing explanations and qualification checklists for the three largest service categories.

Ensure the team can quickly identify the required vehicle information before confirming feasibility.

Track service combinations more consistently so demand for bundled requests is visible instead of fragmented across multiple labels.

Make the requested-service field mandatory at lead creation to reduce the current 20 missing entries.

7. Lead Management & Outcomes

7.1 Current status snapshot

Status group	Leads	Share
In progress	62	37.3%
Appointment confirmed	54	32.5%
Service completed	23	13.9%
Unclassified	10	6.0%
Not feasible	7	4.2%
Cancelled	7	4.2%
Needs review	2	1.2%
Appointment attended – completion unverified	1	0.6%
Total	166	100.0%

69.9%	13.86%	7	7
IN PROGRESS + CONFIRMED	RECORDED COMPLETION RATE	CANCELLED	NOT FEASIBLE

The largest operational pool is made up of 62 in-progress leads and 54 leads with confirmed appointments. Together, these groups represent 116 leads (69.9%). This is a current workload signal: it identifies where follow-up visibility matters most, but it does not mean that 69.9% are 'stuck' or that 13.86% is a historical funnel conversion rate.

7.2 What the status data suggest operationally

- The 62 in-progress leads should be segmented by age, last contact and next action in future tracking so that high-priority follow-ups are visible.
- The 54 confirmed appointments create a clear near-term operational workload; appointment readiness and confirmation routines should be standardized.
- The 10 unclassified leads indicate a reporting gap and should be assigned a controlled status.
- The 2 needs-review cases and the single attended-but-unverified appointment indicate cases where the next outcome is not sufficiently captured.
- The 7 not-feasible leads can be analyzed separately to identify recurring vehicle/service qualification issues.

8. Key Findings

01

Acquisition is concentrated

Messenger + WhatsApp = 116/166 leads (69.9%).

02

WhatsApp shows a strong observed completion association

19 of 53 WhatsApp leads were recorded completed; 19 of 23 total completions came from WhatsApp.

03

High-volume Messenger needs process investigation

63 Messenger leads generated 1 recorded completion; the gap warrants a workflow audit rather than a causal conclusion.

04

Demand is concentrated in three services

Fonctions cachées, Navigation GPS and Apple CarPlay represent 51.8% of all recorded leads.

05

The active pipeline is large

62 leads are in progress and 54 appointments are confirmed, together 69.9% of recorded leads.

06

The recorded completion rate is 13.86%

23 of 166 leads are currently marked Service completed; this is a snapshot metric, not a historical conversion rate.

07

Data quality limits measurement

17 sources, 20 services and 10 statuses are missing or incomplete; this can distort channel and service reporting.

08

September is not directly comparable to earlier months

Only 7 leads are recorded for September, so monthly trend interpretation should remain cautious.

9. Recommendations

The recommendations below are designed to be implementable by a small customer-growth/community-management team. They prioritize operational changes that can be tested and measured rather than assuming that observed correlations are causal.

# / Action	Owner	What to do	Timing	Measure
1. Build a structured follow-up queue	Customer/Community	Create a daily list of in-progress leads with last-contact date, next action, owner and priority. Start with the 62 in-progress leads.	Immediate	% of in-progress leads with a next action
2. Audit the WhatsApp workflow	Community + Management	Document response time, qualification questions, follow-up cadence and handling patterns for the 19 completed WhatsApp leads; compare them with non-completed cases.	Immediate	Median response time; completion by handling pattern
3. Standardize Messenger follow-up	Community	Review why 63 Messenger leads produced only 1 recorded completion. Check response speed, handoff, qualification and follow-up consistency before changing channel strategy.	2–4 weeks	Messenger follow-up rate; recorded completion rate
4. Make source and service mandatory	Operations	Require a lead source and requested service before a lead is considered fully captured. Use controlled dropdown values where possible.	Immediate	Missing-source rate; missing-service rate
5. Create service-specific scripts	Community + Technical	Prepare concise scripts/checklists for Fonctions cachées, Navigation GPS and Apple CarPlay, which together represent 51.8% of demand.	2–4 weeks	Response time; qualified-lead rate
6. Standardize status transitions	Management	Define allowed statuses and the exact condition for moving a lead to each status. Add a required next-step field.	Immediate	Unclassified leads; stale in-progress leads
7. Close the appointment-to-completion loop	Operations	For every confirmed appointment, capture attended / completed / cancelled / no-show and completion date. This turns the current snapshot into a measurable funnel over time.	Next cycle	Appointment-to-completion rate
8. Track lead aging	Management	Add lead age and days since last contact. Use thresholds to identify leads requiring escalation.	Next cycle	Aged-lead share; median time to completion
9. Review not-feasible cases	Technical + Community	Analyze the 7 not-feasible cases by vehicle/service characteristics to identify recurring qualification issues and improve pre-screening.	Monthly	Not-feasible rate by service/vehicle
10. Keep the dashboard as a management routine	Management	Refresh the dashboard on a fixed cadence and review the same KPIs weekly/monthly so that changes are measured consistently.	Ongoing	Trend in volume, active pipeline, completion and data quality

Recommended management cadence

Daily: review new leads and high-priority in-progress leads.

Weekly: review channel volume, follow-up activity, confirmed appointments and completed services.

Monthly: review service demand, not-feasible cases, cancelled cases and data-quality indicators.

After each month: compare channel and service performance using consistent definitions rather than changing metrics retrospectively.

PRIORITY SEQUENCE

1) Make the pipeline actionable,

2) investigate the WhatsApp/Messenger performance gap,

3) improve source/service/status data capture, and 4) build a true historical funnel from future tracking.

10. Limitations

The dataset contains 166 recorded leads from June through September 2026; the September tab contains only 7 recorded leads and may not represent a complete month.

Statuses are a current snapshot. The data do not preserve every historical status transition, so the report does not claim a conventional lead-to-sale conversion funnel.

Recorded completion differs substantially by source, but the dataset does not contain enough contextual variables to establish causality. Differences may reflect customer intent, service mix, response speed, staffing, channel handling or recording practices.

Missing source, service and status values reduce measurement precision.

Repeated phone numbers and VINs were identified but not automatically removed because they may represent repeat customers or multiple service requests.

Some service categories have very small counts. Percentages based on one or two observations should not be treated as stable performance indicators.

No financial value, acquisition cost, response-time, customer satisfaction or customer-level longitudinal history was available in the analyzed dataset.

INTERPRETATION RULE

Use this report to improve the process and measurement system. Do not use the current completion figures as a causal ranking of channels or as a definitive customer-conversion benchmark.

11. Conclusion

The Deblocar Customer & Growth Analytics project converts an operational lead workbook into a structured decision-support workflow. The analysis shows a concentrated acquisition mix, concentrated service demand and a substantial current follow-up pipeline.

The clearest operational signal is the contrast between WhatsApp and Messenger outcomes: WhatsApp contributes 19 of the 23 recorded completions, while Messenger contributes the largest lead volume but only one recorded completion. Rather than interpreting this as proof that one channel is inherently better, the finding should be used to investigate differences in handling, customer intent and measurement practices.

The second major opportunity is pipeline management. With 62 leads in progress and 54 appointments confirmed, the business has a large pool of active cases whose next action and eventual outcome should be made more visible. At the same time, the 17 missing sources, 20 missing services and 10 unclassified statuses show that better data capture is necessary for stronger future decisions.

The recommended next step is therefore not simply more reporting. It is to improve the operating process so that every new lead has a source, requested service, owner, status, next action and—when applicable—an appointment and completion outcome. Once that structure is maintained consistently, Deblocar can move from snapshot reporting to a reliable historical funnel and more rigorous growth measurement.

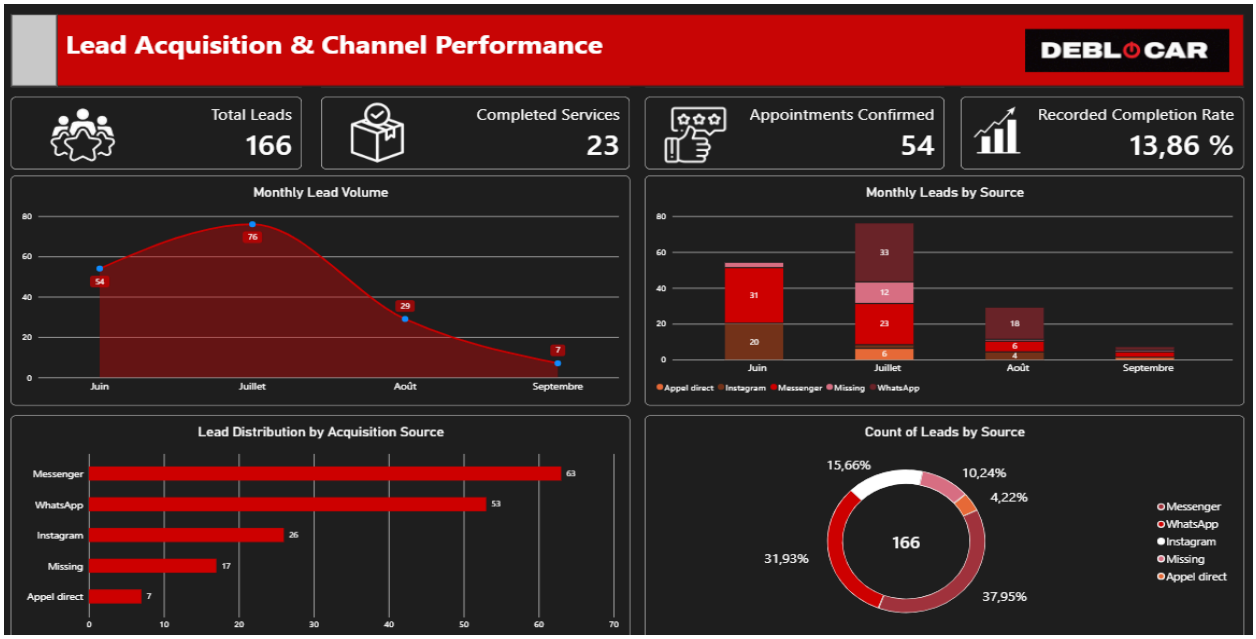

FINAL TAKEAWAY

The dashboard explains what is happening now; the recommended tracking improvements will make it possible to explain why it happens and whether interventions actually improve outcomes.

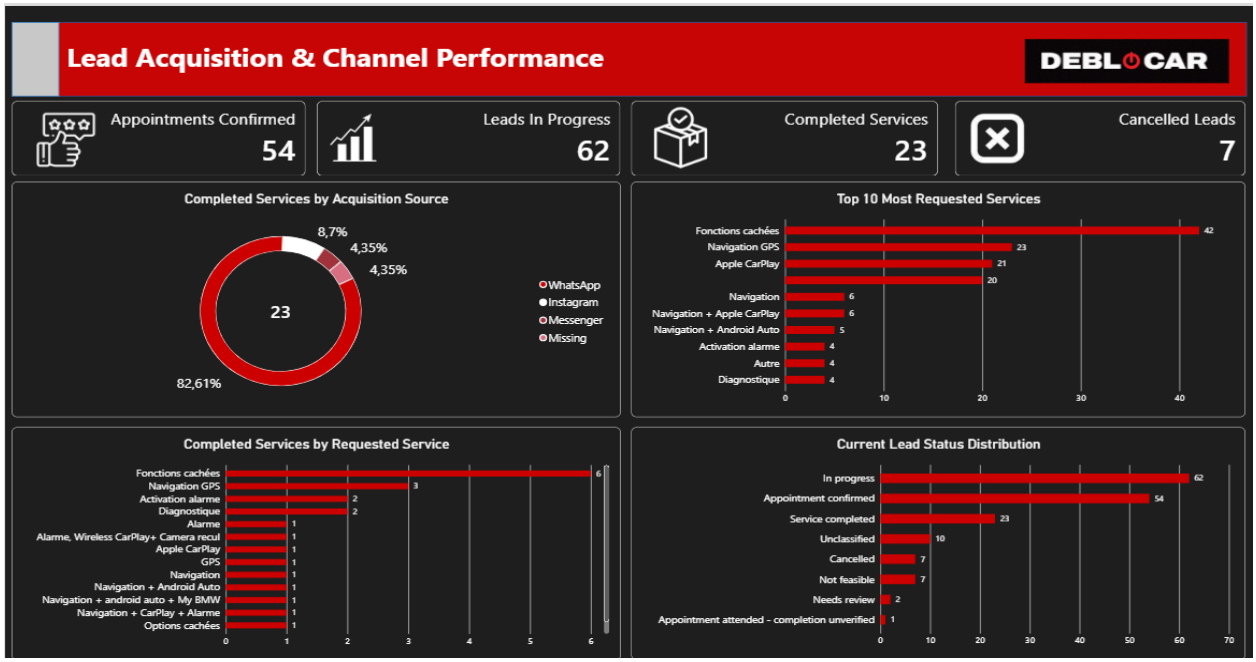

Appendix A — Power BI Dashboard Reference

The dashboard follows the requested red / black / white visual theme and contains two analytical pages.

Page 1 — Lead Acquisition & Channel Performance

Page 2 — Service Demand & Lead Management

Appendix B — SQL Validation Snapshot

The cleaned anonymized dataset was loaded into MySQL as the `deblocar_analytics.leads` table. The SQL layer was used to reproduce the key business metrics used in the report and dashboard.

Validation	Expected / validated value
Total leads	166
Service completed	23
Appointment confirmed	54
In progress	62
Cancelled	7
Not feasible	7
Missing source	17
Missing service	20
Missing status	10

Core SQL workflow

schema.sql defines the database/table structure; **analysis_queries.sql** reproduces the focused business checks used for this report.
